Simultaneous Hand-Eye and Robot-World Calibration by Solving the AX=YB Problem without Correspondence*

Haiyuan Li[1], Qianli Ma[2], Tianmiao Wang[1] and Gregory S. Chirikjian[2]

Abstract—**Calibration is often an important and necessary step in the use of image-guided systems. In the case of the $AX = YB$ problem, the relative hand-eye (X) and robot-world (Y) transformations must be determined to provide accurate data for use in control. As an added difficulty, the exact correspondence between the streams of sensor data (As and Bs) is typically unknown due to asynchrony is sampling rates and processing time. One common scenario is a constant shift between the two data streams. Therefore, in this paper we present a probabilistic method to simultaneously solve for X and Y without a priori knowledge of the correspondence between the streams of As and Bs. We begin by discussing probability density functions on $SE(3)$ and then introduce Euclidean-group invariants to obtain an exact solution for X and Y. Then, we present a method to simultaneously recover X and Y and the correspondence between the shifted data sets. Finally, we numerically simulated the proposed method with shifted, asynchronous data and noise added to the stream of Bs to verify its efficiency and robustness.**

I. INTRODUCTION

Image-guided systems have been widely employed in applications throughout robotics such as robot-assisted surgery, autonomously guided vehicles, etc. Sensors such as a camera, a laser scanner, or an ultrasound probe are usually mounted on the distal end of a robotic manipulator. For a typical "hand-eye" system as described above, the relative transformation between the sensor with respect to the end-effector should be accurately calibrated, and it is often characterized as the well-known **AX=XB** problem. A variation of this problem is the **AX=YB** problem, where both the hand-eye transformation and the pose of the robot base with respect to the world frame need to be calibrated. In a typical environment, the relationships between the sensor frame, robot frame, and world frame are variant and uncertainties exist. Therefore, simultaneous coordinate calibrations have to be determined frequently in order to enable the robotto respond to dynamic environments.

In the **AX=YB** problem, data streams of As and Bs can be respectively obtained via different sensors. The data streams may arrive in an asynchronous fashion due to the different working frequencies of the sensors. This asynchrony causes a shift between the two data streams which removes the correspondence between the As and Bs. In this paper, a novel

Fig. 1. (1) The hand-eye and robot-world calibration problem formulated as AX=YB. (2) The hand-eye calibration problem formulated as AX=XB. (The Universal Robot pictured above is owned by Prof. Emad Boctor of Johns Hopkins University).

method is presented to solve for X and Y without a priori knowledge of the correspondence between the As and Bs.

The hand-eye calibration problem can be modelled as **AX = XB**, where A and B are the homogeneous transformation matrices describing the relative motions of the end-effector and the sensor respectively. As shown in Fig. 1 part (2), $A = A^i(A^{i+1})^{-1}$ and $B = (B^i)^{-1}B^{i+1}$. Given multiple pairs of (A_i, B_i) with correspondence (note that (A_i, B_i) are the relative transformations obtained from the raw data), many deterministic methods have been proposed to solve for X. To the best of the authors' knowledge, Shiu [1] and Tsai [2] are the first to solve the $AX = XB$ sensor calibration problem. The other methods include but are not limited to the quaternion, dual quaternion, screw theory, Lie group theory, convex optimization and gradient descent methods [3]–[9].

All of the methods above assume a priori knowledge of the exact correspondence between A_i and B_i. For data streams $\{A_i\}$ and $\{B_j\}$ that are asynchronous, several methods have been proposed in the literature to solve for X using data without a priori knowledge of the correspondence. These methods assume that there are some corresponding pairs of data in the streams of the $\{A_i\}$ and $\{B_j\}$; however, the exact correspondence is unknown [10]–[12].

Simultaneous estimation of the hand-eye and robot-world transformations has been viewed as the **AX=YB** problem. As shown in Fig. 1 part (1), Y is the transformation from the robot base to the world frame, A denotes the pose of the sensor in the world frame and B is the transformation from the end-effector to its fixed base. The A and B in **AX=YB** are different from those in **AX=XB** where the former uses absolute transformations and the latter uses relative transformations. This problem has been solved by many different methods such as the Kronecker product, quaternion, dual quaternion, and nonlinear optimization methods [13]–[20]. Simulatneous calibration of X and Y can be problematic in that all the methods above assume exact correspondence between $\{A_i\}$ and $\{B_i\}$, which is not the case in the real world, and this is why a simultaneous solution for X and Y in the **AX=YB** problem can be a challenging issue. Another similar problem involves the calibration of multiple robots in terms of hand-eye, tool-flange, and robot-robot transformations, and it is formulated as the **AXB=YCZ** problem [21] which will not be discussed in detail here. In the above methods, the correspondence between A and B is known a priori. In this paper, we focus on one case of the **AX=YB** problem where there is no a priori knowledge of the correspondence between the data streams.

The rest of the paper is organized as follows. In Section II, a novel probabilistic method is presented to solve for eight candidates of X and Y. In Section III, an algorithm involving both correlation theorem and Euclidean group invariants is proposed to recover the correspondence between $\{A_i\}$ and $\{B_j\}$, which is used to select the optimal solution among the candidates. The simulation results obtained by taking noisy data without correspondence are illustrated in Section IV. Finally, conclusions are drawn based on the numerical results and possible future work is pointed out.

II. SOLVING AX=YB USING A PROBABILISTIC METHOD ON MOTION GROUPS

In this section, a brief introduction to the concept of probability density functions (PDFs) on the special Euclidean group $SE(3)$ is presented and the probabilistic representation of $AX = YB$ is derived.

Any rigid body transformation matrix can be viewed as a group element of $SE(3)$:

$$H(R,t) = \begin{pmatrix} R & t \\ 0^T & 1 \end{pmatrix} \in SE(3), \ \ R \in SO(3) \quad (1)$$

where $SO(3)$ denotes the special orthogonal group, $t \in \mathbb{R}^3$ is a translational vector and H is the symbol for the group element.

Given a large set of pairs $(A_i, B_i) \in SE(3) \times SE(3)$ where $i = 1, \cdots, n$, the following equation is true if the correspondence is known as a priori:

$$A_i X = Y B_i. \quad (2)$$

For a group element $H \in SE(3)$, a Dirac delta function $\delta(H)$ is defined to be finite only at the identity and zero elsewhere:

$$\delta(H) = \begin{cases} +\infty, & H = I \\ 0, & H \neq I. \end{cases} \quad (3)$$

The Dirac delta function also satisfies the identity constraint as:

$$\int_{SE(3)} \delta(H)dH = 1. \quad (4)$$

A shifted Dirac delta function can be defined as $\delta_A(H) = \delta(A^{-1}H)$. Given $K, H \in SE(3)$ and two well-defined functions $f_1, f_2 \in (L^1 \cap L^2)(SE(3))$, their convolution on $SE(3)$ is defined as:

$$(f_1 * f_2)(H) = \int_{SE(3)} f_1(K)f_2(K^{-1} \circ H)dK. \quad (5)$$

where $\circ$ denotes the group product, and in this case it is simply matrix multiplication. Employing the properties of the δ function, it is straightforward to see that:

$$(f * \delta)(H) = \int_{SE(3)} f(K)\delta(K^{-1} \circ H)dK = f(H). \quad (6)$$

Therefore, for each A_i and B_i, the following equations can be obtained:

$$(\delta_{A_i} * \delta_X)(H) = \delta(A_i^{-1}HX^{-1}) \quad (7a)$$
$$(\delta_Y * \delta_{B_i})(H) = \delta(Y^{-1}HB_i^{-1}). \quad (7b)$$

Using Eq. (2) and Eq. (3), the above two equations can be combined into a single equation as:

$$(\delta_{A_i} * \delta_X)(H) = (\delta_Y * \delta_{B_i})(H) \quad (8)$$

Defining the PDF of $\{A_i\}$ and $\{B_i\}$ as:

$$f_A(H) = \frac{1}{n} \sum_{i=1}^{n} \delta_{A_i}(H) \quad (9a)$$

$$f_B(H) = \frac{1}{n} \sum_{i=1}^{n} \delta_{B_i}(H) \quad (9b)$$

then by using the distributivity of convolution, adding n instances of Eq. (9), and substituting Eq. (8) in, we have:

$$(f_{A_i} * \delta_X)(H) = (\delta_Y * f_{B_i})(H) \quad (10)$$

If each of the data streams $\{A_i\}$ and $\{B_i\}$ are generated using Gaussian distribution over $SE(3)$, then they can be viewed as "highly-focused". The convolution of two highly-focused PDFs have some interesting properties that can be

used to solve for X. For simplicity, we will drop the integral interval "$SE(3)$" for the remainder of the paper, as it should be self-evident given the integration measure that is used. In particular, the mean M and covariance Σ of a PDF $f(H)$ on $SE(3)$ are defined as:

$$\int log(M^{-1}H))f(H)dH = \mathbb{O} \tag{11a}$$

$$\Sigma = \int log^\vee(M^{-1}H)[log^\vee(M^{-1}H)]^T f(H)dH \tag{11b}$$

where the explicit expression of the matrix logarithm $log(H)$ along with its vectorized form $log^\vee(H)$ are given in [22]. If $f_A(H)$ is given as in Eq. (9), then the corresponding discrete version of the mean M_A and covariance Σ_A will be:

$$\sum_{i=1}^{n} log(M_A^{-1}A_i)) = \mathbb{O} \tag{12a}$$

$$\Sigma = \sum_{i=1}^{n} log^\vee(M_A^{-1}A_i)[log^\vee(M_A^{-1}A_i)]^T. \tag{12b}$$

Given $\{A_i\}$ with the cloud of frames A_i clustering around M_A, an iterative formula can be used for computing M_A [23] as:

$$^{k+1}M_A = {}^k M_A \circ exp[\frac{1}{n}\sum_{i=1}^{n} log(^k M_A^{-1} \circ A_i)] \tag{13}$$

An initial estimate of the iterative procedure can be chosen as $^0 M_A = \frac{1}{n}\sum_{i=1}^{n} log(A_i)$, then a local minimum of M_A is obtained by solving a nonlinear optimization problem with the cost function of $||\sum_{i=1}^{n} log(M_A^{-1}A_i)||^2$. A similar procedure can be used to compute M_B. Σ_A and Σ_B are then straight forward to compute given known M_A and M_B.

The mean and covariance for the convolution $(f_1 * f_2)(g)$ of two highly-focused functions f_1 and f_2 are calculated as in [23]:

$$M_{1*2} = M_1 M_2 \tag{14a}$$

$$\Sigma_{1*2} = Ad(M_2^{-1})\Sigma_1 Ad^T(M_2^{-1}) + \Sigma_2. \tag{14b}$$

where

$$Ad(H) = \begin{pmatrix} R & O \\ \hat{t}R & R \end{pmatrix}.$$

Because X and Y are constant, their corresponding PDF will be $\delta_X(g)$ and $\delta_Y(g)$, of which the mean and covariance are $M_X = X$, $\Sigma_X = \mathbb{O}_{6\times 6}$ and $M_Y = Y$, $\Sigma_Y = \mathbb{O}_{6\times 6}$, respectively. Therefore, the following equations can be obtained using Eq. (14):

$$M_A X = Y M_B \tag{15a}$$

$$Ad(X^{-1})\Sigma_A Ad^T(X^{-1}) = \Sigma_B. \tag{15b}$$

To solve the above equations, Eq. (15a) is decomposed into a rotational equation and a translational equation as follows:

$$R_{M_A} R_X = R_Y R_{M_B} \tag{16a}$$

$$R_{M_A} t_X + t_{M_A} = R_Y t_{M_B} + t_Y. \tag{16b}$$

Σ_A and Σ_B can be decomposed into blocks as $\begin{pmatrix} \Sigma_A^1 & \Sigma_A^2 \\ \Sigma_A^3 & \Sigma_A^4 \end{pmatrix}$ and $\begin{pmatrix} \Sigma_B^1 & \Sigma_B^2 \\ \Sigma_B^3 & \Sigma_B^4 \end{pmatrix}$, respectively. Knowing that $X^{-1} = \begin{pmatrix} R_X^T & -R_X^T t_X \\ 0 & 1 \end{pmatrix}$, then the first two blocks of Eq. (15b) can be written as follows:

$$\Sigma_{M_B}^1 = R_X^T \Sigma_{M_A}^1 R_X \tag{17a}$$

$$\Sigma_{M_B}^2 = R_X^T \Sigma_{M_A}^1 R_X (\widehat{R_X^T t_X}) + R_X^T \Sigma_{M_A}^2 R_X. \tag{17b}$$

Because Eq. (17a) is a similarity transformation between $\Sigma_{M_B}^1$ and $\Sigma_{M_A}^1$, they share the same eigenvalues and can be eigendecomposed into $\Sigma_{M_A}^1 = Q_{M_A}\Lambda Q_{M_A}^T$ and $\Sigma_{M_B}^1 = Q_{M_B}\Lambda Q_{M_B}^T$ where Λ is a diagonal matrix whose diagonal elements are the eigenvalues of $\Sigma_{M_A}^1$ (or $\Sigma_{M_B}^1$), and Q_{M_A} (or Q_{M_B}) is a square matrix whose columns are the corresponding eigenvectors. The following equation is obtained after substituting $\Sigma_{M_B}^1$ and $\Sigma_{M_A}^1$ into Eq. (17a):

$$\Lambda = (Q_{M_A}^T R_X^T Q_{M_B})\Lambda(Q_{M_B}^T R_X Q_{M_A}) = P\Lambda P^T \tag{18}$$

where $P = Q_{M_A}^T R_X Q_{M_B}$. If Q_{M_A} and Q_{M_B} are further constrained to be rotation matrices, then a rotation matrix P that satisfies Eq. (18) can be one of $\mathcal{P}$ or $-\mathcal{P}$:

$$\mathcal{P} = \left\{ \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \right\}. \tag{19}$$

Therefore, there are eight candidates for R_X which can be calculated via $R_X = Q_{M_A} P Q_{M_B}^T$, and the corresponding t_X can be obtained from Eq. (17b). Given known X, Y can be solved from $Y = M_A X M_B^{-1}$. At last, eight candidate pairs of $\{X_k, Y_k\}$ can be obtained as:

$$X_k = \begin{pmatrix} R_{X_k} & t_{X_k} \\ \mathbf{0}^T & 1 \end{pmatrix}, \quad Y_k = \begin{pmatrix} R_{Y_k} & t_{Y_k} \\ \mathbf{0}^T & 1 \end{pmatrix} \tag{20}$$

where $k = 1, 2, ..., 8$.

The problem then becomes selecting the best pair of $\{X_k, Y_k\}$ from the eight candidates. Based on screw theory, it is known that a homogeneous transformation H can be expressed by the four screw parameters $(\theta, d, \mathbf{n}, \mathbf{p})$ that define the $Pl\ddot{u}cker$ coordinates of the screw motion as:

$$H = \begin{pmatrix} e^{\theta\hat{\mathbf{n}}} & (\mathbf{I}_3 - e^{\theta\hat{\mathbf{n}}})\mathbf{p} + d\mathbf{n} \\ \mathbf{0}^T & 1 \end{pmatrix} \tag{21}$$

where θ is the angle of rotation, d is the translation along the rotation axis, $\mathbf{n}$ is the unit vector representing the axis of

rotation and $\mathbf{p}$ is the position of the line to the origin with $\mathbf{p} \cdot \mathbf{n} = 0$.

Moreover, $AX_k = Y_k B$ can be written as $AX_k = X_k(X_k^{-1} Y_k B)$. Defining $B^k = X_k^{-1} Y_k B$, we have $AX_k = X_k B^k$. There exist two Euclidean-group invariant relationships for each pair of $(A_i, B_i^k)(i = 1, \cdots, n; k = 1, \ldots, 8)$ as follows:

$$\theta_{A_i} = \theta_{B_i^k}, d_{A_i} = d_{B_i^k} \qquad (22)$$

Among the eight pairs (X_k, Y_k), one can find an optimal solution which minimizes the cost function defined as:

$$(X, Y) = \underset{(X_k, Y_k)}{\mathbf{arg}min} \frac{1}{n} \sum_{i=1}^{n} (\| \theta_{A_i} - \theta_{B_i^k} \| + \| d_{A_i} - d_{B_i^k} \|) \qquad (23)$$

Eight candidates of (X_k, Y_k) are calculated using the probabilistic method on $SE(3)$, which doesn't require the correspondence between A_i and B_j to be known. However, the correspondences need to be recovered to pick the optimal (X_k, Y_k).

III. SOLUTION WITH UNKNOWN CORRESPONDENCE BETWEEN A_i AND B_j^k

In most cases, the two sets of homogeneous transformations $\{A_i\}$ and $\{B_j\}$ are calculated based on the data obtained from different sensors. Due to the asynchronous timing of the sensor readings, the correspondence between $\{A_i\}$ and $\{B_j\}$ is usually unknown. This section deals with the case where there is a shift between $\{A_i\}$ and $\{B_j\}$, and the Euclidean-group invariants are used to recover the correspondence between the data streams. The advantage of the above probabilistic solution lies in that X and Y can be calculated even if there is no a priori knowledge of the correspondence. However, there are still eight possible candidates of (X_k, Y_k) to choose from and by using Euclidean-group invariants, it is straightforward to determine which is the optimal pair if the correspondence between A_i and B_j^k can be known.

The Discrete Fourier Transform (DFT) decomposes a time-domain signal into its constituent frequencies. The input is a finite list of equally spaced samples of a function. Given a discrete signal consisting of a sequence of N complex numbers $x_0, x_1, \cdots, x_{N-1}$, the DFT is denoted by $X_\kappa = \mathcal{F}(x_n)$ as:

$$X_\kappa = \sum_{n=0}^{N-1} x_n \cdot exp(-i\frac{2\pi}{N}n\kappa). \qquad (24)$$

where i here is the imaginary unit.

The Inverse Discrete Fourier Transform (IDFT) is denoted as:

$$x_n = \frac{1}{N} \sum_{n=0}^{N-1} X_\kappa \cdot exp(i\frac{2\pi}{N}n\kappa). \qquad (25)$$

The discrete convolution of two sequences f_n and g_n is defined as:

$$(f * g)(\tau) = \sum_{j=0}^{N} f(t_j)g(t_j - \tau). \qquad (26)$$

In the convolution theorem, the Fourier transform of a convolution is the product of the Fourier transforms, namely:

$$f * g = \mathcal{F}^{-1}[\mathcal{F}(f) \cdot \mathcal{F}(g)]. \qquad (27)$$

The correlation theorem indicates that the correlation function, $Corr(f, g)$, will be larger for a shift vector where the two sequences f_n and g_n share more similar features. The correlation can be obtained based on the convolution theorem. The DFT of $Corr(f, g)$ is equal to the product of the DFT of f_n and the complex conjugate $\mathcal{F}^*$ of the DFT of g_n:

$$Corr(f, g) = f \star g = \mathcal{F}^{-1}[\mathcal{F}(f) \cdot \mathcal{F}^*(g)]. \qquad (28)$$

Compared to the standard time-domain convolution algorithm, the complexity of the convolution by multiplication in the frequency domain is significantly reduced with the help of the convolution theorem and the Fast Fourier Transform (FFT).

Given two sequences $\{\theta_{A_i}\}$ and $\{\theta_{B_i^k}\}$ corresponding to $\{A_i\}$ and $\{B_i^k\}$, the shift that is needed to recover the data correspondence is obtained as below. Firstly, θ_{Ai} and $\theta_{B_i^k}$ are normalized as:

$$\theta_{1i} = \frac{(\theta_{A_i} - \mu_A)}{\sigma_A}, \theta_{2i} = \frac{(\theta_{B_i^k} - \mu_{B^k})}{\sigma_{B^k}} \qquad (29)$$

where $\mu_A(\mu_{B^k})$ is the mean of $\theta_{A_i}(\theta_{B_i^k})$ and $\sigma_A(\sigma_{B^k})$ is the standard deviation. Here, the correlation function $Corr(\theta_1, \theta_2)$ is the function of the time sequence index n which describes the probability of these two sequences being separated by this particular index. The index corresponding to the maximum of $Corr(\theta_1, \theta_2)$ indicates the amount of shift τ_{shift} between $\{\theta_{A_i}\}$ and $\{\theta_{B_i^k}\}$.

$$\tau_{shift} = \underset{index}{\mathbf{arg}max}(Corr(\theta_1, \theta_2)) \qquad (30)$$

Therefore, the correspondence between the two sequences can be found. The data of θ_{A_i} or d_{A_i} are shifted by $-\tau_{shift}$ to obtain a sequence of new pairs $(\theta_{A_i}(i + \tau_{shift}), \theta_{B_i^k})$ and $(d_{A_i}(i + \tau_{shift}), d_{B_i^k})$, where $max(0, \tau_{shift}) \leq i \leq min(n, n + \tau_{shift})$. The data stream can be shifted back to regain correspondence to synchronize the data streams once the shift is computed, and the optimal solution of X and Y can also be recovered by minimizing the cost function in Eq. (23) using the Euclidean-group invariants as shown in Section II.

IV. SIMULATION STUDIES

For the numerical experiments in this section, the rotational and translational errors for X and Y are measured as $Error(R_X) = \| log^{\vee}(R_{X_{Solved}}^T R_{X_{true}}) \|$, $Error(t_X) = \| t_{X_{Solved}} - t_{X_{true}} \|$, $Error(R_Y) = \| log^{\vee}(R_{Y_{Solved}}^T R_{Y_{true}}) \|$ and $Error(t_Y) = \| t_{Y_{Solved}} - t_{Y_{true}} \|$ respectively.

Fig. 5.   Orientation and translation errors of X and Y versus shift using Li's and Shah's methods without correspondence.

Fig. 3.   Box-and-whisker plots of translational and rotational errors versus the covariance noise on data stream $\{B_i\}$.

Fig. 6.   Orientation and translation errors of X and Y versus shift using Li's and Shah's methods with correspondence.

to $\{B_i\}$, then the maximum of the cross correlation can be used to recover the shift. After that, we can shift the data stream $\{A_i\}$ back to its original position to recover the correct correspondence with $\{B_i\}$, which will be used to find a correct solution satisfying the Euclidean-group invariants as defined in Eq. (22). Therefore, a unique pair of (X_k, Y_k) can be selected to minimize the cost function. In Fig. 2, because the shift between $\{A_i\}$ and $\{B_i\}$ is calculated accurately, the translational and rotational errors fluctuate by only a small amount compared to the errors of the no-shift data streams.

To test the robustness of the proposed method, noises are exerted onto $\{B_i\}$ by employing $B_i^{noise} = B_i \exp(\widehat{\mathbf{x}}_{noise})$, where each element of the Lie Algebra $\mathbf{x}_{noise}$ belongs to the Gaussian distribution defined as $N \sim (\mu_{noise}, \sigma_{noise})$. In Fig. 3, as the covariance noise σ_{noise} increments from 0.01 to 0.08, the errors of R_X, R_Y, t_X, and t_Y increase as shown in the box-and-whisker plot. There are several outliers outside the whiskers, while the median is calculated as the final solved X and Y. Fig. 4 shows the solved (X,Y)s in red and blue with the actual (X,Y) in black with covariance noise of $\sigma = 0.05$ and shift $n = 2$.

The probabilistic method in this paper can recover the correspondence between shifted data streams, which is useful for other sensor calibration methods. In the $AX = YB$ problem, there have been many calibration methods developed for solving X and Y given data streams with correspondence. However, few of them considered the cases without correspondence. When data streams of A and B are shifted or asynchronous, most of these methods fail to give a valid solution. To further test the effectiveness of our method, we shift the data sequence of $\{A_i\}$ by $n = 0, 1, 2, 3, 4, 5$ with respect to the data sequence of $\{B_i\}$. We augment

Fig. 4.   (a) The solved X (in red) and the actual X (in black) for 10 simulation trials with covariance noise of 0.05 and shift of 2.(b) The solved Y (in blue) and the actual Y (in black) for 10 simulation trials with covariance noise of 0.05 and shift of 2.

There are multiple ways of generating the data streams $\{A_i\}$ and $\{B_i\}$. One way is to first generate $\{B_i\}$ and then map it to $\{A_i\}$ using $A = YBX^{-1}$. $\{B_i\}$ can be obtained by randomly sampling on the Lie algebra of B from a zero mean multivariate Gaussian distribution as follows:

$$\delta_i \in \mathcal{N}(\mathbf{0}; \Sigma) \subset \mathbb{R}^6 \tag{31a}$$

$$B_i = \exp(\hat{\delta}_i)\exp(\mu) \tag{31b}$$

where the mean $\mu = \mathbf{0} \in se(3)$ and the covariance matrix $\Sigma \in \mathbb{R}^{6 \times 6}$ is a diagonal matrix with same diagonal elements σ. The hat operator $\hat{\delta}$ converts a 6 by 1 vector into its corresponding Lie algebra. The data stream $\{A_i\}$ can be easily obtained as described above. After employing the proposed probabilistic method, 8 sets of sequences $(\theta_{A_i}, \theta_{B_i^k})$ and $(d_{A_i}, d_{B_i^k})$ can be obtained respectively where $i = 1, \cdots, 100$ and $k = 1, \ldots, 8$.

If the data stream $\{A_i\}$ is shifted by m units relative

other $AX = YB$ solvers with our probabilistic approach. In Li's method [18], X and Y are solved for at the same time while Shah [19] uses separable solutions to solve for X and Y. In Fig. 5, the correspondence between data streams is unknown and the errors on both rotations and translations are significant. After synchronizing the data streams by using the probabilistic method, Li and Shah's methods achieve the same level of performance as in the no-shift situation as shown in Fig. 6.

V. CONCLUSIONS

In this paper, we developed a probabilistic approach to simultaneously obtain X and Y in the $AX = YB$ sensor calibration problem. Without a priori knowledge of the correspondence between $\{A_i\}$ and $\{B_j\}$, the proposed probabilistic method on Lie groups is used to constrain the possible solutions of X and Y to eight pairs of candidates. Given shifted data streams of $\{A_{i+s}\}$ and $\{B_i\}$, using the correlation theorem with Euclidean-group invariants, the correspondence is recovered to determine the correct solution among the eight candidates. In the numerical simulation, the method performs well with different sets of data samples. Future work will be to further develop the existing algorithm to solve for more general asynchronous cases, such as flipped data pairs or missing data in the data streams.
